In Search of Acceptability Criteria:
Database Consistency Requirements and
Transaction Correctness Properties

Abstract

Whereas serializability captures database consistency requirements and transaction correctness properties via a single notion, recent research has attempted to come up with correctness criteria that view these two types of requirements independently. In this paper, we develop a taxonomy of various correctness criteria that focus on database consistency requirements and transaction correctness properties from the viewpoint of what the different dimensions of these two are. This taxonomy allows us to categorize correctness criteria that have been proposed in the literature. To help in this categorization, we have applied a uniform specification technique, based on ACTA, to express the various criteria. Such a categorization helps shed light on the similarities and differences between different criteria and to place them in perspective.

1 INTRODUCTION

database consistency requirements capture correctness from the perspective of objects in the database — as transactions perform operations on the objects. On the other hand, transaction correctness properties capture correctness from the perspective of the structure and behavior of transactions. That is, they deal, for example, with the results of transactions and the interactions between transactions. Serializability [Eswaran, 1976] captures database consistency requirements and transaction correctness properties via a single notion: (1) The state of the database at the end of a set of concurrent transactions is the same as the one resulting from some serial execution of the same set of transactions; (2) The results of transactions and the interactions among the set of transactions are the same as the results and interactions, had the transactions executed one after another in this serial order. As applications using databases become more complex, the correctness criteria that are acceptable to the application become more complex and hence harder to capture using a single correctness notion.

Recent research has attempted to come up with correctness criteria, or acceptability criteria, that view these two types of requirements independently. An early example is nested transactions [Moss, 1981], in which the database consistency requirements are captured by requiring the serializability of independent (sub)transactions; additional transaction structural properties specify the correctness of subtransactions of individual nested transactions. The search for more flexible correctness requirements is further motivated by the introduction of other transaction models that extend the traditional atomic transaction model. (See [Elmagarmid, 1991] for a description of some of the extended transaction models.) These extensions came about because the atomic transaction model in conjunction with serializability is found to be very constraining when applied in advanced applications such as design databases that function in distributed, cooperative, and heterogeneous environments.

Proposed correctness criteria range from the standard serializability notion to eventual consistency [Sheth, 1990]. Quasi-serializability [Du, 1989], predicatewise serializability [Korth, 1988b], etc., are points that lie within this range. Eventual consistency can be viewed as a "catch-all" term with different connotations: For example, requiring consistency “at a specific real-time”, “within some time” or “after a certain amount of change to some data”, or enforcing consistency “after a certain value of the data is reached”, etc. Whereas serializability and its relaxations are, in general, application and transaction model independent criteria, eventual consistency, as the examples above show, are application and transaction model specific. It is not difficult to see that these relaxed correctness requirements are useful within a single database as well as in multi-database environments.

Whereas serializability works under the simple assumption that individual transactions maintain the consistency of the database, proposed correctness criteria require more from the transaction developers. In particular, a transaction may have to be aware of the functionality of other transactions, especially in a cooperative environment. This makes transaction development as well as management more difficult. Our goal in this paper is to understand the conceptual similarities and differences between different correctness criteria without getting into the practical implications of adopting them.
So, in this paper we examine database consistency constraints and transaction correctness properties from the viewpoint of what the different dimensions of these two types of correctness are. This taxonomy allows us to categorize existing proposals thereby shedding some light on the similarities and differences between the proposals and to place them in perspective. The categorization also helps us determine whether or not a correctness notion is transaction model specific or application specific. We will see that even though some of the correctness notions were motivated by specific transaction models or specific applications, they have broader applicability.

To help in this categorization, we apply a uniform specification technique to express the various correctness criteria that have been proposed. The technique is based on the ACTA formalism [Chrysanthis, 1990, 1991] which heretofore has been used for the specification of and for reasoning about extended transactions. One of the key ingredients of ACTA is the idea of constraining the occurrence of significant events associated with transactions, Begin, Abort, and Split, for example. These constraints are expressed in terms of necessary and sufficient conditions for events to occur. These, in turn, relate to the ordering of events and the validity of relevant conditions. Such constraints can also facilitate the specification of database consistency requirements and transaction correctness properties. The ACTA formalism is introduced in Section 3.

The rest of the paper is structured as follows: Subsection 2.1 provides a taxonomy of database consistency requirements while 2.2 provides a taxonomy of transaction correctness properties. A specification of existing proposals as well as their categorization (based on the taxonomy) is the subject of Section 4. Section 5 concludes the paper with some discussions of the next step in this work.

2 A TAXONOMY OF CORRECTNESS CRITERIA

We study different dimensions of the two aspects of correctness, namely, consistency of database state and correctness of transactions, in order to develop a taxonomy of correctness criteria. For concreteness, we give examples as the taxonomy is developed.

2.1 DATABASE CONSISTENCY REQUIREMENTS

Database consistency requirements can be examined with respect to two issues with further divisions of each as discussed below.

- **Consistency Unit:**
  - **Complete Database:**
    All the objects in the database have to be consistent locally as well as mutually consistent, i.e., they should satisfy all the database integrity constraints typically specified in the form of predicates on the state of the objects. Semantics of the objects can be taken into account to improve concurrent access to the objects while maintaining consistency [Chrysanthis, 1991a].
Example: Traditional serializability (SR) applied to atomic transactions [Bernstein, 1987].

- Subsets of the objects in the database:
  * Location-independent subsets:
    The database is viewed as being made up of subsets of objects. The subsets are not necessarily disjoint and are specified as part of the database definition. Each object in the database is expected to be consistent locally but mutual consistency is required only for objects that are within the same subset.
    Example: Setwise serializability (SSR) applied to compound transactions [Sha, 1985] and Predicatewise serializability (PSR) applied to cooperative transactions [Korth, 1988].
  * Location-dependent subsets:
    Each subset corresponds to one of the sites of a (distributed / heterogeneous) database. In addition to mutual consistency among objects in a subset (i.e., site), consistency among subsets is also required depending on which parts of a database are accessed by a transaction.

- Individual Objects:
  Each object in the database is expected to be consistent locally.

• Consistency Maintenance:
  This is related to the issues of when a consistency requirement is expected to hold and how consistency is restored if it does not hold.

  - When is a consistency requirement expected to hold?
    * At activity boundaries: (An activity denotes a unit of work)
      - When an operation completes:
        When an operation on an object completes, the necessary consistency specifications must hold.
        Example: Concurrent processes accessing shared objects.
      - When a set of operations completes:
        When a set of operations performed by a transaction completes, the necessary consistency is expected to hold.
      - When a transaction completes:
        Consistency is expected to hold upon a transaction’s completion.
        Example: Atomic transactions.
      - When a set of transactions completes:
        Consistency is expected to hold not when individual transactions complete but when a set of transactions completes.
    * At specific points of time:
      Consistency is required only at/after specific points in time. This is an example of temporal consistency [Sheth, 1990].
Example: A bank account is expected to be made consistent, with respect to the debits and credits that occur on a given day, upon closing of business.

* At specific states:
  Objects may be required to be mutually consistent only when a certain number of updates have been made to one of the objects or a state satisfying a certain predicate is reached.
  Example: A centralized database of a department store chain may require updates only upon the completion of 100 sales at a particular store. Such requirements are referred to as spatial consistency in [Sheth, 1990].

- If a consistency requirement does not hold at a point it is supposed to, how is it restored?
  * Impossible:
    This applies when the consistency requirement must hold at activity boundaries. The activity is allowed to complete only if the requirement holds, i.e., completion is delayed until consistency holds. If an activity cannot complete successfully while maintaining consistency, it is aborted or compensated.
    Example: SR, PSR, QSR, and cooperative serializability (CoSR), applied to atomic, nested, and distributed transactions.
  * Consistency is restored in a deferred manner:
    This typically applies when consistency is expected in certain states or at certain times. When it is applied to consistency that is expected at an activity boundary, the activity is allowed to complete and restoration is begun subsequently.
    - Eventually:
      Consistency between objects must be restored eventually.
      Example: If mutual consistency is required between two objects and one is changed by a transaction, another can be triggered to make changes in the other object.
    - By a certain time:
      A deadline may be imposed on the time by which consistency is restored.
      Example: In real-time systems, the state of the controlled environment should be reflected in the internal state of the controlling system within a certain time so that appropriate and timely control can be exercised.

2.2 TRANSACTION CORRECTNESS PROPERTIES

As was mentioned in the introduction, serializability suffices as a correctness criterion for traditional atomic transactions since once individual transactions are guaranteed to take one consistent database state to another consistent state, serializability guarantees that a set of concurrent transactions when started in a consistent state take the database to another consistent state. So the only transaction correctness property of interest is: Each transaction when executed by itself must maintain database consistency. From this it follows that, under serializability, the output of
a transaction reflects a consistent database state. However, more elaborate correctness properties have been proposed in the context of additional application requirements and newer transaction models. These transaction correctness properties can be discussed with respect to three criteria:

- **Correctness of transaction results:**
  - **Absolute:**
    The output of transactions must reflect a consistent database state.
    *Example:* SR applied to atomic transactions, QSR applied to distributed transactions.
  - **Relative:**
    Outputs of a transaction are considered correct even if they do not reflect a consistent state of the object, as long as they are within a certain bound of the result that corresponds to the consistent state.
    *Example:* Epsilon-serializability (ESR) [Pu, 1991] applied to Epsilon-transactions, approximate query processing [Hou, 1989].

- **Correctness of transaction structure:**
  Correctness depends on the (structural) relationship between transactions. This is typically specified in terms of prescribed and/or proscribed commit, abort, begin, and other types of dependencies [Chrysanthis, 1991] between transactions. Since structural properties are governed by a particular transaction model, the specifications of the model express these requirements.

- **Correctness of data access related transaction behavior:**
  Transactions are required to perform operations on objects in a certain manner to be considered correct. That is, these requirements are constraints on the history of concurrent operations.
  *Example:* To satisfy serializability, conflict relationship between transactions – as they access data concurrently – must be acyclic. Patterns [Skarra, 1991] are more application specific correctness requirements that reflect the (semantics of) usage of the object.

- **Correctness of temporal behavior of transactions:**
  Transactions have start time and completion time (deadline) constraints.
  *Example:* Transactions in real-time systems.

The taxonomy just presented shows how the various correctness requirements can be viewed from the perspectives of database consistency and transaction correctness. It is perhaps clear that, from a database application designer's perspective, what is required is to specify which leaves of the taxonomy correspond to his/her application and then provide additional specifications required by the individual leaves. For instance, if correctness depends on transactions' structural properties, additional specifications will be needed to specify what these properties are. For example, if transactions in an application behave according to the nested transaction model, an axiomatic specification of the nested transaction model [Chrysanthis, 1991] will supplement the identification of the fact that transactions have structure related correctness requirements.
We revisit the correctness notions in Section 4.1 where serializability related correctness notions are formally specified and categorized along the different dimensions of the taxonomy. Sections 4.2 and 4.3 deal with the formal specification of more general correctness criteria that are not directly related to serializability but deal, for example, with transaction structure and behavior, specific states of objects, or specific times.

3 A QUICK INTRODUCTION TO THE ACTA FORMALISM

ACTA is a first-order logic based formalism. As mentioned earlier, the idea of significant events underlies ACTA's specifications. Section 3.1 discusses these events. Specifications involve constraints on the occurrence of individual significant events as well as on the history of occurrence of these events. Hence the notion of history and the necessary and sufficient conditions for the occurrence of significant events are introduced in Section 3.2. Finally, Section 3.3 shows how sharing of objects leads to transaction inter-relationships which in turn induces certain dependencies between concurrent transactions.

3.1 SIGNIFICANT EVENTS ASSOCIATED WITH TRANSACTIONS

During the course of their execution, transactions invoke operations on objects. Also, they invoke transaction management primitives. For example, atomic transactions are associated with three transaction management primitives: Begin, Commit and Abort. The specific primitives and their semantics depend on the specifics of a transaction model [Chrysanthis, 1991]. For instance, whereas the Commit by an atomic transaction implies that it is terminating successfully and that all of its effects on the objects should be made permanent in the database, the Commit of a subtransaction of a nested transaction implies that all of its effects on the objects should be made persistent and visible with respect to its parent and sibling subtransactions. Other transaction management primitives include Spawn, found in the nested transaction model [Moss, 1981], Split, found in the split transaction model [Pu, 1988], and Join, a transaction termination event also found in the split transaction model.

**Definition 3.1:** Invocation of a transaction management primitive is termed a significant event. A transaction model defines the significant events that transactions adhering to that model can invoke.

The set of events invoked by a transaction \( t \) is a partial order with ordering relation \( <_t \) where \( <_t \) denotes the temporal order in which the related events occur.

\( ts(e) \) gives the time of occurrence of event \( e \) according to a globally synchronized clock\(^1\). Clearly, \( ts(\beta) \) will be larger than \( ts(\alpha) \) if \( \alpha \) appears earlier in the partial

---

\(^1\)This is obviously as abstraction – the effects of realizing this by a set of closely synchronized clocks on individual nodes in a distributed system will not be discussed here.
order. Further, no two significant events that relate to the same transaction can occur with the same ts value.

3.2 HISTORY, PROJECTION OF THE HISTORY, AND CONSTRAINTS ON EVENT OCCURRENCES

The concurrent execution of a set of transactions $T$ is represented by the history [Bernstein, 1987] of the events invoked by the transactions in the set $T$ and indicates the (partial) order in which these events occur. The partial order of the operations in a history is consistent with the partial order of the events of each individual transaction $t$ in $T$.

The projection of a history $H$ is a subhistory that satisfies a given criterion. For instance,

- The projection of a history $H$ with respect to a specific transaction $t$ yields a subhistory with just the events invoked by $t$. This is denoted by $H_t$.
- The projection of a history $H$ with respect to a specific time interval $[i, j]$ yields the subhistory with the the events which occurred between $i$ and $j$ (inclusive) and is denoted by $H^{[i,j]}$.
  
  When $i$ = system initiation time, we drop the first element of the pair. Thus $H_j = H^{[\text{system init time}, j]}$ denotes all the events that occur until time $j$.

Consistency requirements imposed on concurrent transactions executing on a database can be expressed in terms of the properties of the resulting histories.

The occurrence of an event in a history can be constrained in one of three ways: (1) An event $e$ can be constrained to occur only after another event $e'$; (2) An event $e$ can occur only if a condition $c$ is true; and (3) a condition $c$ can require the occurrence of an event $e$.

**Definition 3.2:** The predicate $e \rightarrow e'$ is true if event $e$ precedes event $e'$ in history $H$. It is false, otherwise. (Thus, $e \rightarrow e'$ implies that $e \in H$ and $e' \in H$.)

**Definition 3.3:** $(e \in H) \Rightarrow \text{Condition}_H$, where $\Rightarrow$ denotes implication, specifies that the event $e$ can belong to history $H$ only if $\text{Condition}_H$ is satisfied. In other words, $\text{Condition}_H$ is necessary for $e$ to be in $H$. $\text{Condition}_H$ is a predicate involving the events in $H$.

Consider $(e' \in H) \Rightarrow (e \rightarrow e')$. This states that the event $e'$ can belong to the history $H$ only if event $e$ occurs before $e'$.

**Definition 3.4:** $\text{Condition}_H \Rightarrow (e \in H)$ specifies that if $\text{Condition}_H$ holds, $e$ should be in the history $H$. In other words, $\text{Condition}_H$ is sufficient for $e$ to be in $H$.

We now describe some common types of constraints.

1. $(\text{Commit}_{t_i} \in H) \Rightarrow ((\text{Commit}_{t_i} \in H) \Rightarrow (\text{Commit}_{t_i} \rightarrow \text{Commit}_{t_j}))$. This says that if both transactions $t_i$ and $t_j$ commit then the commitment of $t_i$ precedes
the commitment of \( t_j \). This Commit-Dependency is indicated by \((t_j, CD, t_i)\). In general, \( (Commit_{t_j} \in H) \Rightarrow condition \) specifies that condition should hold for \( t_j \) to commit.

2. \((Abort_{t_j} \in H) \Rightarrow (Abort_{t_i} \in H)\) i.e., if \( t_i \) aborts then \( t_j \) aborts, states the Abort-Dependency of \( t_j \) on \( t_i \) \((t_j, AD, t_i)\). In general, \( (condition \Rightarrow (Abort_{t_j} \in H)) \) specifies that if condition holds \( t_j \) aborts.

3. \((Begin_{t_j} \in H) \Rightarrow (Begin_{t_i} \rightarrow Begin_{t_j})\) states that transaction \( t_j \) cannot begin executing until transaction \( t_i \) has begun.

### 3.3 Objects, Operations, and Conflicts

A transaction accesses and manipulates the objects in the database by invoking operations specific to individual objects. It is assumed that an operation always produces an output (return value), that is, it has an outcome (condition code) or a result. The result of an operation on an object depends on the current state of the object. For a given state \( s \) of an object, we use \( return(s, p) \) to denote the output produced by operation \( p \), and \( state(s, p) \) to denote the state produced after the execution of \( p \).

**Definition 3.5:** Invocation of an operation on an object is termed an object event. The type of an object defines the object events that pertain to it. We use \( p_t[ob] \) to denote the object event corresponding to the invocation of the operation \( p \) on object \( ob \) by transaction \( t \). Object events are also part of the history \( H \).

**Definition 3.6:** Let \( H^{(ob)} \) denote the projection of the history with respect to the operations on \( ob \). Two operations \( p \) and \( q \) conflict in a state produced by \( H^{(ob)} \), denoted by \( conflict(H^{(ob)}, p, q) \), iff

\[
\begin{align*}
\text{(state}(H^{(ob)} \circ p, q) & \neq \text{state}(H^{(ob)} \circ q, p)) \lor \\
\text{return}(H^{(ob)}, q) & \neq \text{return}(H^{(ob)} \circ p, q)) \lor \\
\text{return}(H^{(ob)}, p) & \neq \text{return}(H^{(ob)} \circ q, p))
\end{align*}
\]

Two operations that do not conflict are compatible.

(\( \circ \) denotes functional composition; \( H \circ p \) appends \( p \) to history \( H \).) Thus, two operations conflict if their effects on the state of an object are not independent of their execution order (first clause) or their return values are not independent of their execution order (second and third clauses). From now on, we drop the first parameter of conflict, namely, \( H^{(ob)} \).

### 4 Specification and Categorization of Correctness Criteria

In this section, we study various database consistency requirements and transaction correctness properties that have been proposed and place them in perspective, given the taxonomy of the previous section. Broadly speaking, Section 4.1 deals with
transaction model and application independent correctness criteria (even though, as we will see, those who proposed them may have had a specific transaction model or application in mind), Section 4.2 discusses transaction model dependent but application independent criteria, and Section 4.3 examines transaction and application dependent consistency requirements. (For a complete axiomatic semantics of the various extended transaction models, the reader is referred to [Chrysanthis, 1991].)

4.1 TRANSACTION AND APPLICATION INDEPENDENT CRITERIA

In general, transaction and application independent correctness criteria are extensions to serializability. In this section, we first specify some of these extensions using the formalism described in the previous section and then use the specifications to show how the different extensions relate to each other. All of these criteria are based on the notion of conflicts and their preservation in equivalent histories. Thus, we do not discuss correctness criteria such as view serializability [Yannakakis, 1984] that are not as easy to realize.

Definition 4.7: Let $R$ be a binary relation on a set of transactions $T$, $t_i$, $t_k \in T$, $t_i \neq t_k$. $R^*$ is the transitive-closure of $R$; i.e.,
$$(t_i R^* t_k) \text{ if } [(t_i R t_j) \vee \exists t_j \in T \{(t_i R' t_j) \wedge (t_j R^* t_k)]}.$$  

4.1.1 Serializability

In traditional databases, serializability and, in particular, conflict serializability, is the well-accepted criterion for concurrency control.

Let $C$ be a binary relation on transactions in $T$.

Let $H$ be the history of events relating to committed transactions in $T$.

Definition 4.8: $\forall t_i, t_j \in T, t_i \neq t_j,$
$$(t_i C t_j) \text{ if } \exists \overline{ob} \overline{ob} \exists p, q \text{ (conflict($p_i$, $\overline{ob}$), $q_j$, $\overline{ob}$)} \wedge (p_i[\overline{ob}] \rightarrow q_j[\overline{ob}]).$$

Definition 4.9: $H$ is (conflict) serializable iff $\forall t \in T, \neg(t C^* t)$.

To illustrate the practical implications of these definitions, note that the $C$ relation captures the fact that two transactions have invoked conflicting operations on the same object and the order in which they have invoked the conflicting operations. Consequently, the $C$ relation captures direct conflicts between transactions in a history as well as their serialization order. The fact that a serialization order is acyclic is stated by requiring that there be no cycles in the $C$ relation.

Note also that the above definitions do not involve any significant events. This reflects the fact that serializability per se does not constrain the occurrence of any significant event, e.g., a Commit event to happen only after another Commit event. (If the $C$ relationship between transactions is acyclic, transactions in $H$ can commit in any order.) That is, the commit order of transactions is not necessarily the same as their serialization order and hence, the commit order cannot be used to
induce the serialization order. However, a commit order induced by a \( C \) relation is consistent with the serialization order. For example, consider the case of rigorous histories [Breitbart, 1991] such as the ones produced by the strict two-phase locking protocol [Eswaran, 1976]. In this case, if transactions \( t_i \) and \( t_j \) have a \( C \) relationship, i.e., they have invoked conflicting operations, a commit dependency [Chrysanthis, 1991] forms between \( t_i \) and \( t_j \). (Conflicting operations may also produce abort dependencies between the invoking transactions; but an abort dependency implies a commit dependency.) By requiring that the \( C \) relation be acyclic, commit dependencies must also be acyclic. By inducing a commit dependency between every pair of transactions invoking conflict operations, the commit order specified by the commit dependencies is the same as the serialization order.

With respect to the taxonomy of Section 2, for serializability, the consistency unit is the complete database, and consistency is required at transaction boundaries. Absolute correctness of transaction results is expected. Atomic transactions and top-level transactions of nested transactions, for example, behave according to the serializability correctness criterion.

The semantics of the operations on the objects (for example, see [Badrinath, 1990][Herlihy, 1987][O'Neil, 1986]) can be used to define the conflict relationship between operations. Furthermore, different degrees of consistency [Gray, 1975] can be ensured by ignoring some of the conflicts. The resulting inconsistencies can be accommodated in applications that can cope with such inconsistencies or when these are masked by the structuring of the objects used by the applications. The former is the case in [Gray, 1975] and with ESR [Pu, 1991] (see [Ramamritham, 1991b] for a formal characterization of ESR). The latter is the case with abstract serializability – used in the context of multi-level transactions [Beeri, 1989][Moss, 1986][Martin, 1988][Badrinath, 1990].

4.1.2 Predicatewise Serializability

Predicatewise serializability has been proposed in [Korth, 1988, 1988b] as the correctness criterion for concurrency control in databases in which consistency constraints are in a conjunctive normal form. In such cases, consistency constraints can be maintained by requiring serializability only with respect to objects which relate to a disjunctive clause.

Let \( P = (P_1 \land P_2 \ldots \land P_n) \) be the database consistency constraint. Suppose the disjunctive clause \( P_k \) relates to objects in \( D_k \subseteq DB \), where \( DB \) is the database.

\( \forall k \in \{1 \ldots n\}, \) let \( C_k \) be a binary relation on transactions in \( T \).

Let \( H \) be the history of events relating to committed transactions in \( T \):

**Definition 4.10:** \( \forall k \in \{1 \ldots n\}, \forall t_i, t_j \in T, t_i \neq t_j, \)

\[ (t_i \ C_k \ t_j), \text{ if } \exists o \in D_k \exists p,q \left( \text{conflict}(p_i[ob], q_j[ob]) \land (p_i[ob] \rightarrow q_j[ob]) \right). \]

**Definition 4.11:** \( H \) is predicatewise serializable iff

\[ \forall t \in T \forall D_k \ 1 \leq k \leq n - (t \ C_k^* \ t) \]

In [Sha, 1985], each \( D_k \) is said to be an atomic data set. With respect to the
taxonomy, for predicatewise serializability, an atomic data set [Sha, 1985] forms a consistency unit and consistency is required at transaction boundaries. Absolute correctness of transaction results is expected. Compound transactions [Sha, 1985] behave according to the predicatewise serializability correctness criterion.

4.1.3 Cooperative Serializability

We define cooperative serializability (CoSR) with respect to a set of transactions which maintain some consistency properties. Transactions form cooperative transaction sets. A cooperative transaction set could be formed by the components of an extended transaction or transactions collaborating over some objects while maintaining the consistency of the objects. In such cases, consistency can be maintained if other transactions which do not belong to the set are serialized with respect to all the transactions in the set. In other words, a set of cooperative transactions becomes the unit of concurrency with respect to serializability.

Let \( T_c \) be a set of cooperative transactions, \( T_c \subseteq T \).

Let \( C_c \) be a binary relation on transactions in \( T \).

Let \( H \) be the history of events relating to committed transactions in \( T \).

**Definition 4.12:** \( \forall t_i, t_j, t_k \in T; t_i \neq t_j, t_i \neq t_k, t_j \neq t_k \forall T_c \subseteq T \) \((t_i, C_c t_j)\), if

\[
\exists ob \exists p q ( (t_i \notin T_c, t_j \notin T_c) (\text{conflict}(p_i, [ob], q_j, [ob]) \land (p_i, [ob] \rightarrow q_j, [ob]))) \lor \\
(t_i \notin T_c, t_j \in T_c, t_k \in T_c) (\text{conflict}(p_i, [ob], q_k, [ob]) \land (p_i, [ob] \rightarrow q_k, [ob]))) \lor \\
(t_i \in T_c, t_j \notin T_c, t_k \in T_c) (\text{conflict}(p_i, [ob], q_k, [ob]) \land (p_i, [ob] \rightarrow q_k, [ob])))
\]

In this definition, the first clause expresses how a dependency between two transactions which do not belong to the same set is directly established when they invoke conflicting operations on a shared object. This is similar to the clause in the classical definition of (conflict) serializability. The other two clauses reflect the fact that when a transaction establishes a dependency with another transaction, the same dependency is established between all the transactions in their corresponding cooperative transactions sets. These clauses can be viewed as expressions of the development of dependencies between transaction sets.

**Definition 4.13:** \( H \) is cooperative serializable iff

\[
\forall t \in T \sim (t \sim C^*_c t)
\]

With respect to the taxonomy of the previous section, for cooperative serializability, the consistency unit is the complete database, consistency is required when an ordinary transaction (not a member of a \( T_c \)) completes or a set of cooperating transactions complete. Absolute correctness of transaction results is expected. The correctness requirement expressed informally in [Martin, 1992] corresponds to CoSR.

4.1.4 Quasi Serializability

Quasi Serializability has been proposed in [Du, 1989] as a correctness criterion for maintaining transaction consistency in multidatabases, e.g., heterogeneous distributed databases. In these systems, transactions can either execute on a single
site (called local transactions), or can execute on multiple sites (called global transactions).

In QSR, the correctness of the execution of a set of global and local transactions is based on the notion of a quasi serial history which, unlike a serial history, specifies that only global transactions are executed serially. A history is quasi serial if (1) all local histories are (conflict) serializable, and (2) there exists a total order of all global transactions $g_m$ and $g_n$ where $g_m$ precedes $g_n$ in the order and all $g_m$'s operations precede $g_n$'s operations in all local histories in which they both appear. A quasi serializable history is equivalent to a quasi serial history.

Let $G$ be the set of global transactions and $g_n^i$ be a (sub)transaction of a global transaction $g_n \ (g_n \in G)$ executing all the operations of $g_n$ on site $i$.

Let $T_i$ be the set of transactions, both local transactions and global (sub)transactions, executing on site $i$. $T = (\cup_i T_i)$.

Let $H$ be the history of events relating to committed transactions in $T$.

Let $R$ be a binary relation on a set of global transactions $G$.

**Definition 4.14:** Let $g_m, g_n \in G, g_m \neq g_n$, $(g_m \ R \ g_n)$ if

\[ \exists k, g_m^k, g_n^k \ (g_m^k \ C \ g_n^k) \ \exists p, t_0 = g_m^k, t_p = g_n, \forall i, 0 \leq i \leq p-2 \]

\[ \exists ob, \exists p, q \ (\text{conflict}(p, ob), t_{i+1}^q = t_p \ \land \ (p, ob) \rightarrow t_{i+1}^q \ [ob])) \land \]

\[ \exists ob, \exists p, q' \ (\text{conflict}(p', ob'), t_{i+2}^q = t_{i+1}^q \ \land \ (p', ob') \rightarrow t_{i+2}^q \ [ob'])) \land \]

\[ (t_{i+1}^q \ [ob] \rightarrow p_{i+1}^q [ob])) \]

where $C$ is the binary relation defined in Definition 4.8.

The $C$ relation captures the fact that two global transactions directly conflict in a local history when they invoke conflicting operations on a share object. Two global transactions might also indirectly conflict in a local history even if they don't access any share objects. Indirect conflicts are introduced by other transactions that directly conflict with each other and with the global transactions. These, indirect conflicts between two transactions, particularly those introduced by local transactions, are captured by the second clause of the definition of $R$. Note that this clause, and consequently $R$, is not equivalent to the transitive-closure of $C$ which does not place any restriction on the execution ordering of the conflicting operations, but $R \subset C$.

**Definition 4.15:** $H$ is quasi serializable iff

1. $\forall i \ \forall t \in T_i \ (t \ R^* t)$, and
2. $\forall g \in G \ (g \ R^+ g)$

It should be pointed that since the $R$ relation captures both direct and indirect conflicts between two global transactions in a history, the serializable execution of global transactions is in terms of both direct and indirect conflicts. Indirect conflicts between local transactions induced by conflicts of global transactions that execute

\[ \text{That is, at most one (sub)transaction of a global transaction can execute on a particular site.} \]
on multiple sites are not captured by either clause, the reason being that QSR assumes no data dependency across sites.

With respect to the taxonomy of the previous section, for Quasi serializability, (site-based) subsets of the database objects form the consistency units (i.e., objects in each site form a subset) and consistency should hold when a transaction completes. Absolute correctness of transactions' results is expected. Quasi serializability has been proposed in the context of distributed (multi-database) transactions.

4.1.5 Relationship between different Serializability-based Correctness Criteria

Thus far in this section, we have specified four serializability-based correctness criteria using the ACTA formalism and classified them with respect to our taxonomy in Section 2. Here, we will use the formal definitions of the various criteria to relate them to each other.

According to predicatewise serializability, each \( D_k \) is associated with a \( C_k \) and hence conflicting transactions can be serialized differently with respect to different \( D_k \). This is contrary to serializability which permits only a single system-wide serialization order involving conflicting transactions based on \( C \). However, if \( D_k \) is the complete database, then \( C = C_k \), and consequently, predicatewise serializability is equivalent to serializability.

In the case of cooperative serializability, transactions in different cooperative transaction sets may be related by the \( C_c \) relation (individual transactions not belonging to any cooperative set can be viewed as singleton Cooperative transaction sets). Hence, if each cooperative transaction set has just one member, then \( C_c = C \) and, in this case, cooperative serializability is equivalent to serializability.

In the case of quasi-serializability, there are two distinct conditions under which QSR is equivalent to serializability. These correspond to the situations in which one of the two clauses of the definition of QSR is trivially true: (1) In the absence of global transactions, transactions in \( T_i \) are serialized based only on \( C \). (2) In the absence of local transactions, transactions in \( T_i \) are serialized based only on \( R \), i.e., here \( R = C \). Indirect conflicts due to local transactions are not possible whereas indirect conflicts due to global transactions are considered by \( C'' \).

Finally, we would like to point out that these different correctness criteria can be combined and/or adopted within a single database. For instance, it is easy to picture how cooperative serializability can be used in conjunction with predicatewise serializability and how cooperative serializability can be used in conjunction with even quasi-serializability.

For such combinations of correctness criteria, their specification can be derived from the specification of the individual correctness criteria. As an example, let us examine one way that cooperative serializability can be combined with quasi-serializability in order to support a multirelational system in which component databases allow local transactions to form cooperative groups. In this case, according to cooperative serializability, global (sub)transactions as well as other local transactions that do not belong to a cooperative set, are serialized with respect to all the transactions in the set. The formal definition of this combined criterion is derived from the
As mentioned earlier, different transaction models produce different transaction structures where the structure of an extended transaction defines its component transactions and the relationships between them. Dependencies can express these relationships and thus, can specify the links in the structure. For example, in hierarchically-structured nested transactions, the parent/child relationship is established at the time the child is spawned. This is expressed by a child transaction $t_c$ establishing a weak-abort dependency (defined below) on its parent $t_p$ ($(t_c \ WD t_p)$) and by a parent establishing a commit dependency on its child ($(t_p \ CD t_c)$). The weak-abort dependency guarantees the abortion of an uncommitted child if its parent aborts whereas the commit dependency prevents a child from committing after its parent has committed.

In [Chrysanthis, 1991] and [Chrysanthis, 1992] we gave axiomatic definitions of different transaction models in terms of dependencies that occur between transactions that conform to a particular model. So we now formally specify some of the dependencies that can occur in addition to the Commit Dependency, Abort Dependency, and Begin Dependency specified in Section 3.2.

Let $t_i$ and $t_j$ be two transactions and $H$ be a finite history which contains all the events pertaining to $t_i$ and $t_j$.

Weak-Abort Dependency $(t_j \ WD t_i)$: if $t_i$ aborts and $t_j$ has not yet committed,
then \( t_j \) aborts. In other words, if \( t_j \) commits and \( t_i \) aborts then the commitment of \( t_j \) precedes the abortion of \( t_i \) in a history, i.e.,

\[
(\text{Abort}_{t_i} \in H) \Rightarrow (\neg (\text{Commit}_{t_j} \rightarrow \text{Abort}_{t_i}) \Rightarrow (\text{Abort}_{t_j} \in H)).
\]

**Strong-Commit Dependency** \((t_j \text{ SCD } t_i)\): if transaction \( t_i \) commits then \( t_j \) commits; i.e.,

\[
(\text{Commit}_{t_i} \in H) \Rightarrow (\text{Commit}_{t_j} \in H).
\]

**Termination Dependency** \((t_j \text{ TD } t_i)\): \( t_j \) cannot commit or abort until \( t_i \) either commits or aborts; i.e.,

\[
(\text{ Commit}_{t_i} \in H) \Rightarrow (\epsilon \rightarrow \epsilon')
\]

where \( \epsilon \in \{\text{ Commit}_{t_i}, \text{ Abort}_{t_i}\} \), and \( \epsilon' \in \{\text{ Commit}_{t_j}, \text{ Abort}_{t_j}\}\).

**Exclusion Dependency** \((t_j \text{ E D } t_i)\): if \( t_i \) commits and \( t_j \) has begun executing, then \( t_j \) aborts (both \( t_i \) and \( t_j \) cannot commit); i.e.,

\[
(\text{ Commit}_{t_i} \in H) \Rightarrow (\langle \text{ Begin}_{t_i} \in H \Rightarrow \text{ Abort}_{t_j} \in H \rangle).
\]

**Force-Commit-on-Abort Dependency** \((t_j \text{ CAD } t_i)\): if \( t_i \) aborts, \( t_j \) commits; i.e.,

\[
(\text{ Abort}_{t_i} \in H) \Rightarrow (\text{ Commit}_{t_j} \in H).
\]

**Serial Dependency** \((t_j \text{ SD } t_i)\): transaction \( t_j \) cannot begin executing until \( t_i \) either commits or aborts; i.e.,

\[
(\text{ BEGIN}_{t_i} \in H) \Rightarrow (\epsilon \rightarrow \text{ BEGIN}_{t_j})
\]

where \( \epsilon \in \{\text{ Commit}_{t_i}, \text{ Abort}_{t_i}\}\).

**Begin-on-Commit Dependency** \((t_j \text{ BCD } t_i)\): transaction \( t_j \) cannot begin executing until \( t_i \) commits; i.e.,

\[
(\text{ BEGIN}_{t_i} \in H) \Rightarrow (\text{ Commit}_{t_j} \rightarrow \text{ BEGIN}_{t_j}).
\]

**Begin-on-Abort Dependency** \((t_j \text{ BAD } t_i)\): transaction \( t_j \) cannot begin executing until \( t_i \) aborts; i.e.,

\[
(\text{ BEGIN}_{t_i} \in H) \Rightarrow (\text{ Abort}_{t_j} \rightarrow \text{ BEGIN}_{t_j}).
\]

**Weak-begin-on-Commit Dependency** \((t_j \text{ WCD } t_i)\): if \( t_i \) commits, \( t_j \) can begin executing after \( t_i \) commits; i.e.,

\[
(\text{ BEGIN}_{t_j} \in H) \Rightarrow (\langle \text{ Commit}_{t_i} \in H \Rightarrow (\text{ Commit}_{t_i} \rightarrow \text{ BEGIN}_{t_j}) \rangle).
\]

Let us look at further examples of structure-related transaction correctness properties. In the transaction model proposed in [Buchmann, 1990, Garcia-Molina, 1991] a parent can commit only if its vital children commit, i.e., a parent transaction has an abort dependency on its vital children \( t_v \) \((t_p \text{ AD } t_v)\). Child transactions may also have different dependencies with their parents if the transaction model supports various spawning or coupling modes [Dayal, 1990]. Sibling transactions may also be interrelated in several ways. For example, components of a saga [Garcia-Molina, 1987] can be paired according to a compensated-for/compensating relationship [Korth, 1990]. Relations between a compensated-for and compensating transactions as well as those between them and the saga can be specified via begin-on-commit dependency \( \text{ BCD } \), begin-on-abort dependency \( \text{ BAD } \), force-commit-on-abort dependency \( \text{ CAD } \) and strong-commit dependency \( \text{ SCD } \) [Chrysanthis, 1992]. In a similar fashion, dependencies that occur in the presence of alternative transactions and contingency transactions [Buchmann, 1990] can also be specified [Chrysanthis, 1992].

With respect to the taxonomy, an application that uses an extended transaction model will have correctness requirements related to transactions’ structure where these requirements are specified via axioms that express the dependencies that are formed when transactions execute according to the given model.
4.3 TRANSACTION AND APPLICATION DEPENDENT CRITERIA

We now focus on the required behavior of a transaction and hence on the requirements imposed by the application that employs that specific transaction. We distinguish between two types of behavior related properties:

1. Those that relate to constraints on a transaction's access to objects. Some of these are mandated by the concurrency properties of the objects. For instance, as discussed in Section 4.1, serializability demands acyclic C relationships. Here we will discuss additional access requirements.

2. Those that relate to properties that deal with its other behavioral properties, such as, when a transaction can/must begin and when it can/must end. Spatial and temporal requirements are related to this type.

We elaborate upon the first type through an example. Consider a page object with the standard read and write operations, where read and write operations conflict. A read's return-value is dependent on a previous write, whereas a write's return-value is independent of a read or another write. In addition, consider transactions which have the ability to reconcile potential read-write conflicts: When a transaction ti reads a page x and another transaction tj subsequently writes x, ti and tj can commit in any order. However, if tj commits before ti commits, ti must reread x in order to commit. This is captured by the following requirement:

\[(\text{read}_{t_i}(x) \rightarrow \text{write}_{t_j}(x)) \Rightarrow ((\text{Commit}_{t_j} \rightarrow \text{Commit}_{t_i}) \Rightarrow (\text{Commit}_{t_j} \rightarrow \text{read}_{t_i}(x))).\]

In this example, ti has to reread the page x when, subsequent to the first read, the page is written and committed by tj. In general, ti may need to invoke an operation on the same or a different object. For instance, instead of x, ti may have to read a scratch-pad object which ti and tj use to determine and reconcile potential conflicts. In general, the specification of correct transaction behavior can include the specification of operations that need to be controlled to produce correct histories as well as the specification of operations that have to occur in correct histories. These correspond to conflicts and patterns in [Skarra, 1991].

Let us now turn to other behavioral specifications, for example, those that concern the beginning and termination of transactions. Consider the following simple requirement which states that if condition is true then transaction tj must begin.

\[\text{condition} \Rightarrow (\text{Begin}_{t_j} \in H)\]

condition can depend on the occurrence of an event, on the state of the database, and on time. As we will see, the above requirement can be used for the flexible enforcement of consistency, to trigger the propagation of changes, to react to consistency violations, and to notify changes. Thus, the above specification can be considered to be a specification for the automatic triggering of situation-dependent actions, e.g., for expressing the rules that govern the triggering of actions in an active database [Dittrich, 1991].

Suppose condition is related to the occurrence of some significant event within a transaction ti. In this case, the additional structural relationships (for instance, the
different coupling modes [Dayal, 1990]) between $t_i$ and $t_j$ can be specified via the dependencies discussed in Section 4.2.

If \textit{condition} relates to the state of the database, what we have is related to \textit{spatial consistency} discussed in [Sheth, 1990]. For instance, consider the following \textit{condition}: “One hundred sales have occurred at this store since the master database at the store’s headquarters was last updated.”

If \textit{condition} relates to time, for instance, if \textit{condition} is “time > 8pm”, we have a \textit{temporal consistency} requirement.

Now let us consider situations where \textit{constraints} are placed on the beginning of transactions. For example, a transaction $t_i$ to compute daily interest can start after midnight but only after the day’s withdrawals and deposits have been reflected in the account (say by a transaction $t_j$). This can be specified as

\[(ts(\text{Begin}_{t_i}) \geq 12\text{am}) \land (t_i \land BCD \land t_j)\]  

This is an example where a transaction has a time-based start-dependency as well as a begin-on-commit dependency on another transaction.

Let us consider another example. If a deposit is made by time $x$ then the transaction that reflects it in the account should not be started until time $y$. This is specified by

\[((\text{Commit}_{t_i} \in H) \land (ts(\text{Commit}_{t_i}) < x)) \Rightarrow ((\text{Begin}_{t_j} \in H) \Rightarrow (ts(\text{Begin}_{t_j}) > y))\]  

Through several examples, we now consider requirements and constraints associated with the termination of transactions.

Sometimes, we may want to specify that some specific change of state (by one transaction) triggers [Dayal, 1990] another transaction (that perhaps fixes the inconsistency resulting from the first transaction). Clearly, this type of constraint is related to deferred consistency restoration. This can occur, for example, if we had two versions of a database, one which was complete and another (at perhaps a different site) which only contained data required at that site. The two are not required to be consistent at all times but changes done to the complete database are required to percolate to the other within a specified delay. If the changes should be reflected within $d$ units of time, we have the following “temporal commit dependency”:

\[((\text{Commit}_{t_i} \in H) \land (ts(\text{Commit}_{t_i}) = t)) \Rightarrow (\text{Commit}_{t_j} \in H^{t+d})\]  

This says that if $t_i$ commits at time $t$, $t_j$ should commit by time $t + d$. For another example, consider the following:

\[(\text{temperature} \geq \text{threshold} \land \text{time} = t) \Rightarrow (\text{Commit}_{t_j} \in H^{t+\text{function(temperature)}})\]  

Here $t_j$ could be a transaction that opens a valve to pass more coolant into the reactor whose temperature is above threshold. The length of time available to complete this transaction is a function of the current temperature. This is a form of triggered transaction but with specific time constraints imposed on its completion [Korth, 1990b]. Such time constrained activities occur in real-time databases [Ramanamirtham, 1992].
In some situations, it may be desirable to specify an interval \([l, u]\) such that \(t_j\) does not commit before \(l\) (the lower bound) but definitely commits before \(u\) (the upper bound). For example, consider deposits into a bank account. During the day, if a deposit is made before 3pm, it is just "logged" into a file but is reflected in the appropriate account between 10pm and 4am that night. Such constraints take the form

\[
((\text{Commit}_{t_i} \in H) \land (ts(\text{Commit}_{t_i}) < t)) \Rightarrow (\text{Commit}_{t_j} \in H^{l,u})
\]

The above conditions imposed on the initiation and termination of transactions can be viewed as generalizations of the preconditions and postconditions associated with specific transactions [Korth, 1988b].

For a final example of behavior related specifications, consider the situation in which it may be desirable to prevent a transaction \(t_i\) from aborting after a time \(t\). This corresponds to the assumption that a transaction is implicitly committed if it has not aborted by a certain time [Rusinkiewicz, 1990]. For example, no bets can be canceled after a race is started and a lottery ticket cannot be refunded after a given time.

\[
(\text{Abort}_{t_i} \notin H^t) \Rightarrow (\text{Commit}_{t_i} \in H^{t+1})
\]

Other examples of behavior related requirements appear in [Ramamritham, 1991].

5 CONCLUSIONS

In this paper, we have examined different types of acceptability criteria and have attempted to provide a taxonomy with respect to database consistency requirements and transaction correctness properties. Given space limitations, we could examine, in detail, only a subset of the proposals that have been made to capture the correctness properties applicable to extended transaction models as well as those demanded by the newer database applications.

We have approached the problem of categorizing the different proposals by formally specifying them using the framework of ACTA. This allows us to clearly see where one proposal differs from another and what its relationship with serializability is.

We believe this taxonomy to be a good starting point in our endeavor to classify proposed correctness criteria and to compare and contrast them. It can be viewed as a common framework with respect to which one can study where a new correctness criterion fits and how it relates to existing criteria. In this regard, we expect the taxonomy to evolve as better understanding is gained about the correctness needs of emerging database applications.

Let us now examine some of the other implications of this work. In the context of a multi-database system, the specifications of database consistency and transaction correctness can be viewed as requirements on the coordinator of the blackboxes [Breitbart, 1990] that control individual databases. We would like to apply the reasoning capabilities of the ACTA formalism to study the properties of mechanisms, such as in [Sheth, 1991], for maintaining relaxed correctness properties of interdependent data. In the same context, we would like to investigate ways in
which the ACTA primitives themselves can be used as part of these mechanisms [Rusinkiewicz, 1991, Sheth, 1992]. Similarly, in the context of active databases, we can see how the semantics of the rules that govern the triggering of actions can be formally specified. In addition, the relationships between the triggering action and the triggered action can also be expressed precisely using dependencies. Just as we were able to reason about extended transactions using ACTA [Chrysanthis, 1991], we see the formalization of different aspects of active databases as the starting point for addressing issues, such as, reasoning about the consequences of rule firings, changes to rules, and coupling modes.
